Laplace Transform

By definition, Laplace transform of a function f(t) is given as:

$$F(s) = \int_0^\infty f(t)e^{-st}dt \tag{1}$$

where F(s) is called an *image* of the function.

The study of Laplace transform is a separate mathematical field with applications in solving ODEs, which we won't cover. However, we will consider transform of one case of interest - transform of a derivative.

LAPLACE TRANSFORM OF A DERIVATIVE

Consider a derivative $\frac{dx}{dt}$ and its transform:

$$\mathcal{L}\left(\frac{dx}{dt}\right) = \int_0^\infty \frac{dx}{dt} e^{-st} dt \tag{2}$$

we will make use of the integration by parts formula:

Integration by parts

$$\int v \frac{du}{dt} dt = vu - \int \frac{dv}{dt} u dt \tag{3}$$

In our case, $\frac{du}{dt} = \frac{dx}{dt}$, u = x, $v = e^{-st}$, $\frac{dv}{dt} = -se^{-st}$:

$$\mathcal{L}\left(\frac{dx}{dt}\right) = \left[xe^{-st}\right]_0^\infty - \int_0^\infty -se^{-st}xdt \tag{4}$$

$$\mathcal{L}\left(\frac{dx}{dt}\right) = -x(0) + s\mathcal{L}(x) \tag{5}$$

DERIVATIVE OPERATOR

Thus, assuming that x(0) = 0 and denoting $\mathcal{L}(x) = X(s)$, we can obtain a *derivative operator*:

$$\mathcal{L}\left(\frac{dx}{dt}\right) = s\mathcal{L}(x) = sX(s) \tag{6}$$

This form of a derivative operator is very simple to use in practice.

TRANSFER FUNCTION

Consider the following ODE, where u is an input (function of time that influences the solution of the ODE):

$$\ddot{x} + a\dot{x} + bx = u \tag{7}$$

We can rewrite it using the derivative operator:

$$s^2X(s) + asX(s) + bX(s) = U(s)$$
(8)

and then collect x on the left-hand-side:

$$X(s) = \frac{1}{s^2 + as + b}U(s) \tag{9}$$

This form is called a transfer function.

TRANSFER FUNCTION

Examples

Example

Given ODE: $2\ddot{x} + 5\dot{x} - 40x = 10u$

The transfer function for it looks: $X(s) = \frac{10}{2s^3 + 5s - 40}U(s)$

Example

Given ODE: $2\dot{x} - 4x = u$

The transfer function for it looks: $X(s) = \frac{1}{2s-4}U(s)$

Example

Given ODE: $3\ddot{x} + 4x = u$

The transfer function for it looks: $X(s) = \frac{1}{2s^3+4}U(s)$

TRANSFER FUNCTION

Interesting things done easy

Consider the following (strange) ODE:

$$2\ddot{x} + 3\dot{x} + 2x = 10\dot{u} - u \tag{10}$$

Using the differential equation:

$$2s^{2}X(s) + 3sX(s) + 2X(s) = 10sU(s) - U(s)$$
 (11)

...which is the same as:

$$(2s^{2} + 3s + 2)X(s) = (10s - 1)U(s)$$
(12)

The transfer function for it looks:

$$X(s) = \frac{10s - 1}{2s^2 + 3s + 2}U(s) \tag{13}$$

STATE-SPACE TO TRANSFER FUNCTION CONVERSION

Transfer functions are being used to study the relation between the input and the output of the dynamical system.

Consider standard form state-space dynamical system:

$$\begin{cases} \dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u} \\ \mathbf{y} = \mathbf{C}\mathbf{x} + \mathbf{D}\mathbf{u} \end{cases}$$
 (14)

We can rewrite it using the derivative operator:

$$\begin{cases} s\mathbf{I}\mathbf{x} - \mathbf{A}\mathbf{x} = \mathbf{B}\mathbf{u} \\ \mathbf{y} = \mathbf{C}\mathbf{x} + \mathbf{D}\mathbf{u} \end{cases}$$
 (15)

and then collect **x** on the left-hand-side: $\mathbf{x} = (s\mathbf{I} - \mathbf{A})^{-1}\mathbf{B}\mathbf{u}$ and finally, express y out:

$$\mathbf{y} = \left(\mathbf{C}(s\mathbf{I} - \mathbf{A})^{-1}\mathbf{B} + \mathbf{D}\right)\mathbf{u} \tag{16}$$

Transfer Function and Control (0)

Let the dynamic system be described as a transfer function:

$$Y(s) = G(s)X(s) \tag{17}$$

We can try to modify the input based on how the output looks. Since we always do it in a linear way, we can write it as:

$$Y(s) = G(s)(X(s) - H(s)Y(s))$$
 (18)

where H(s)y is called feedback.

How would the transfer function from X(s) to Y(s) look like?

Transfer Function and Control (1)

From
$$Y(s) = G(s)(X(s) - H(s)Y(s))$$
 we go:

$$Y(s) = G(s)X(s) - G(s)H(s)Y(s)$$
(19)

$$Y(s) + G(s)H(s)Y(s) = G(s)X(s)$$
(20)

$$Y(s) = \frac{G(s)}{1 + G(s)H(s)}X(s)$$
 (21)

Thus, we found *closed-loop* transfer function:

$$W(s) = \frac{G(s)}{1 + G(s)H(s)}$$
(22)
